(Paper on arXiv with full details!)

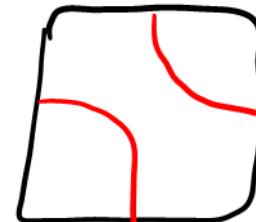

A game: Cube addition

Consider a (rounded) cube with some curves drawn on it.

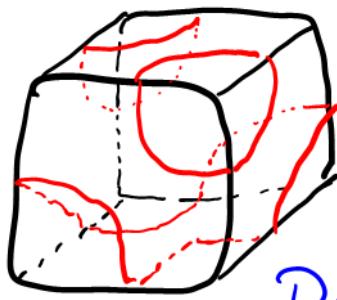

→ On each (rounded) face, curves must appear as

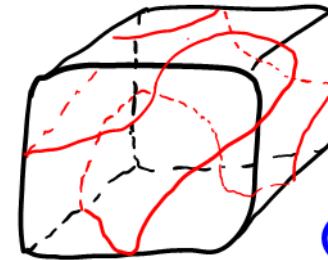

or

E.g.

or

Connected!

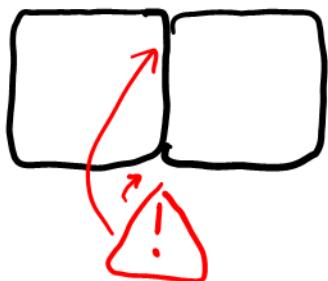

Aim: Keep curves "as connected as possible" under certain rules!

The rules of the game: Gluing, corners, rounding

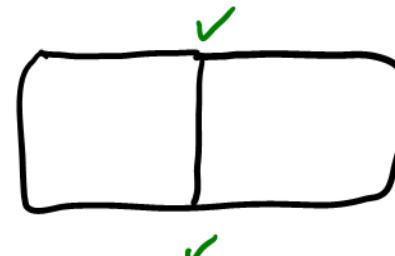

Try to glue together cubes to preserve connectedness,

But...

- * Cubes must glue together smoothly ...

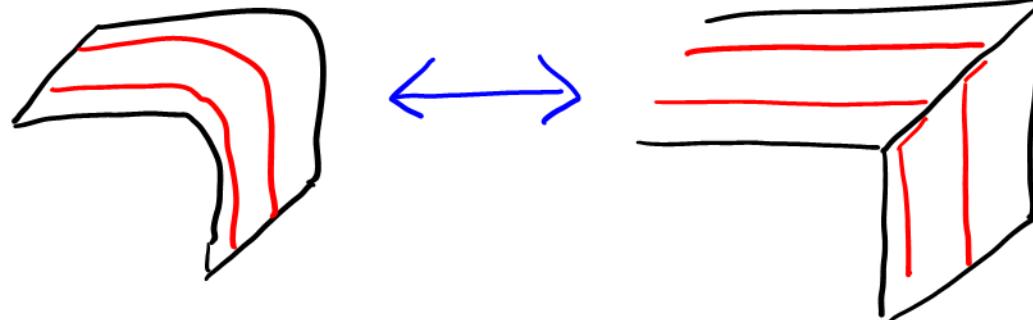

is not smooth!

is...

- * We can sharpen a cube along edges (...any closed embedded 1-submanifold)

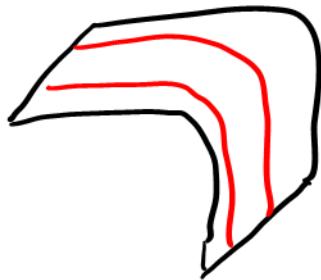

Rule :

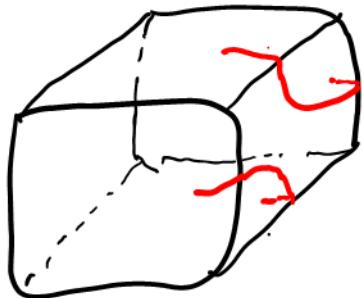

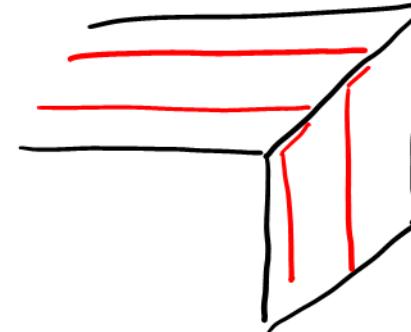

- * We can glue faces together if curves match & result is smooth
(up to isotopy in face)

How gluing works

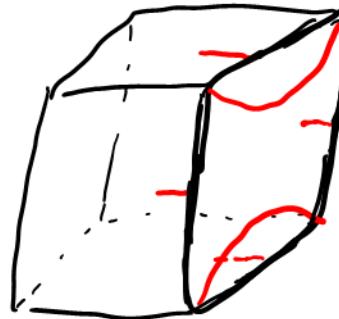

Rule :

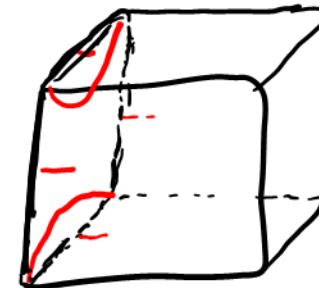

Sharpen!
→
← Round!

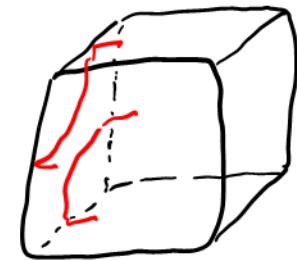

Sharpen!

Glue!

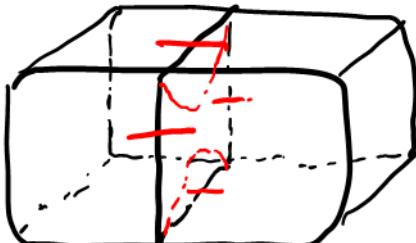

Round!

Rounded cubes glue along a face (after sharpening) iff their curves agree
to disagree!

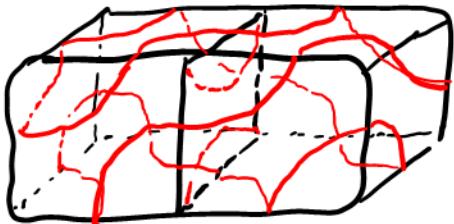

Result :

Contact Cubes

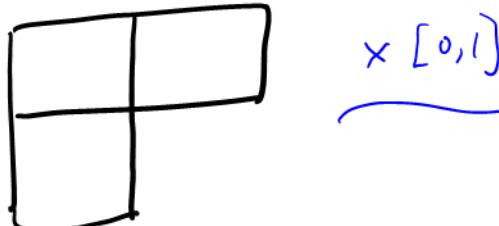

Defn: A calulated contact structure consists of a collection of cubes with curves, as described above, glued together along faces according to rates described above.

E.g.

We will restrict to calculated contact structures where cubes are glued along side faces only, ie as a
 $(\text{gluing of squares})^* \times [0, 1]$

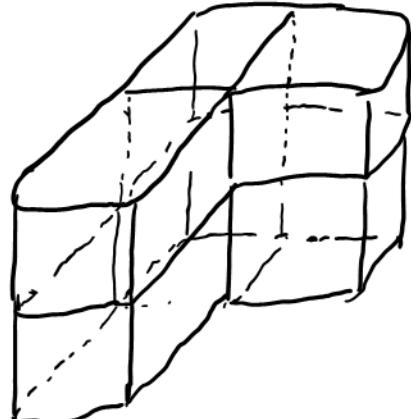

E.g.

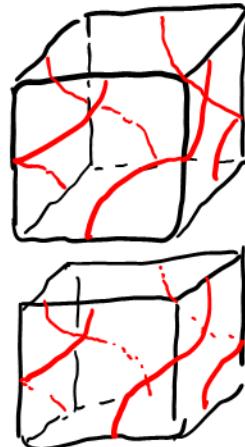

(* Actually to get this all to work certain conditions must be imposed on how squares glue)

Stacking

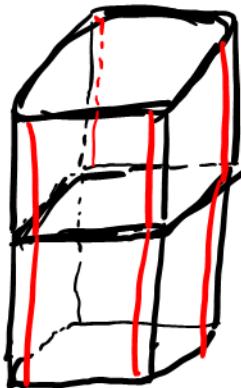

Our calculated contact structures can be stacked on top of each other!

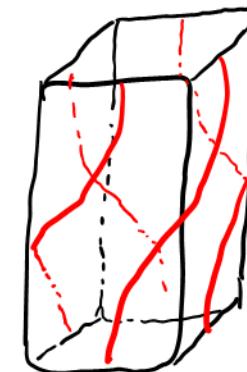

Cubes with curves stack nicely if curves around outside are vertical...

Sharpen!

Round!

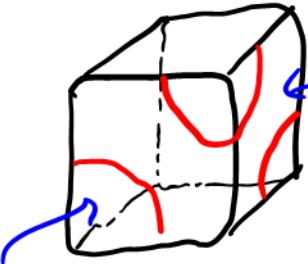

Defn: The curves on a side face are called vertical or unused if they appear as in the above pictures.
(Otherwise, horizontal or used.)

Stackable cubulated contact structures

Note that on a cube, some sides might be used, others unused.

E.g.

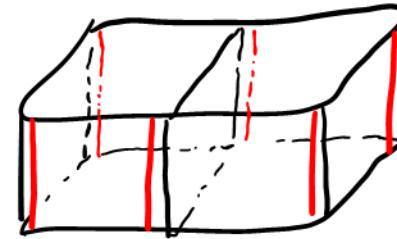

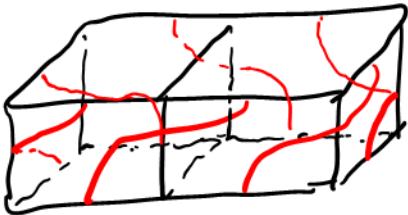

Unused!

Used!

Defn: A cubulated contact structure is stackable if all its exterior side faces are vertical / unused.

E.g.

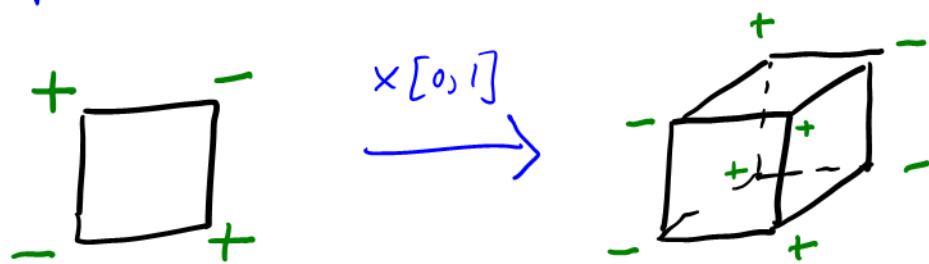

Game: * For a given cube arrangement, how can we arrange curves to be "always connected"?

* When we stack cubes, when do the curves stay connected?

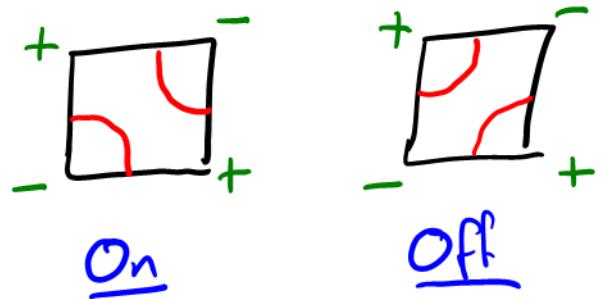

Some Notation

To keep track of curves on top & bottom, introduce signs on vertices of squares.

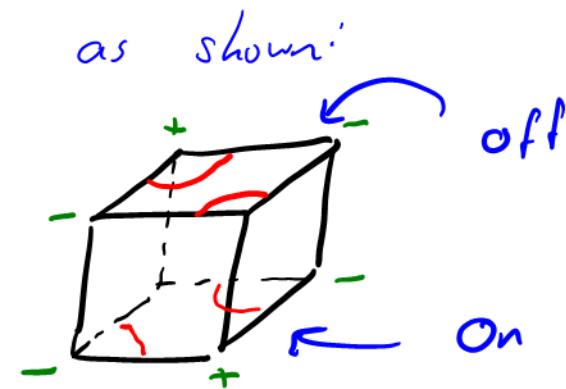

Note this restricts arrangements of squares
E.g. impossible.

Curves on top/bottom are called on or off as shown:

E.g.

S_0 : A stackable cubulated contact structure is completely determined by choices of

- * each top & bottom face on or off
- * each interior side face used or unused.

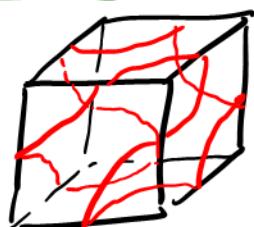

How to win: Tight contact structures

It's very easy to put curves on cubes which become disconnected.

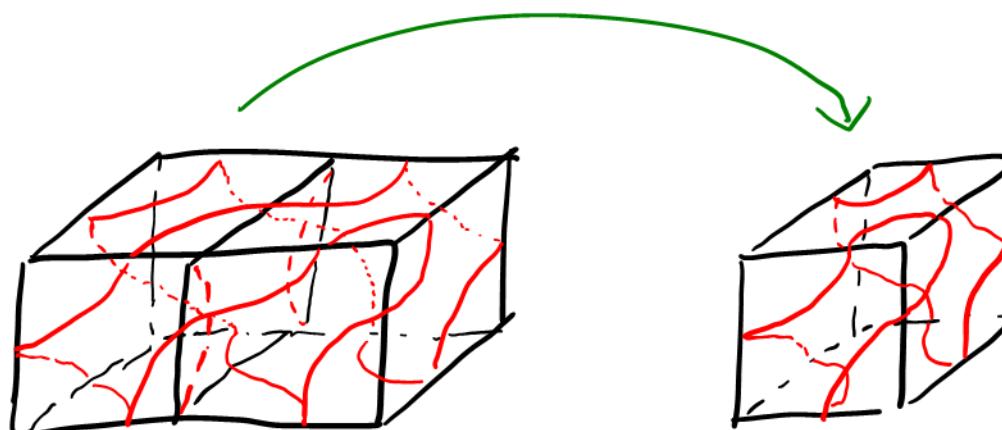

The challenge is to place curves which always remain connected.

Def'n: A stackable cubulated contact structure (s.c.c.s.) is tight if for all subsets of cubes which glue up to give a ball topologically, the curves on the boundary of the ball are connected.

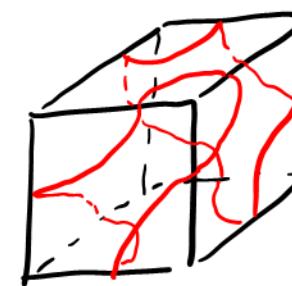

Examples:

Tight!

Not tight!

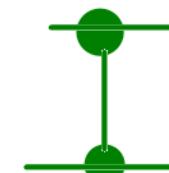

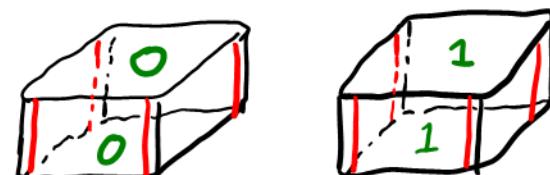

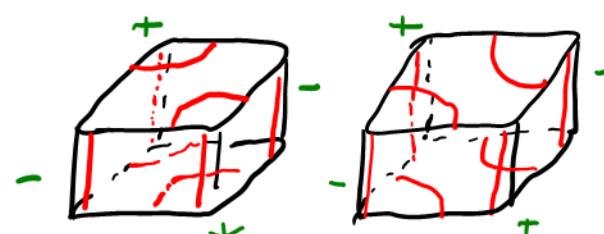

Algebra of cube addition / contact structures

Defn: For a cube arrangement (square arrangement) Q ,
the Contact Category Algebra $CA(Q)$ is the \mathbb{Z}_2 -algebra:

- * freely generated as a \mathbb{Z}_2 -module by tight s.c.c.s. on Q
- * with multiplication defined by stacking s.c.c.s. ($\text{non-tight} = 0$).

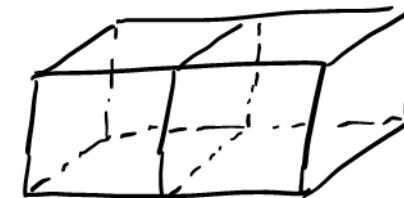

E.g. 1 cube $Q = \begin{array}{c} + \\ \boxed{} \\ - \end{array}$

$$CA(Q) = \mathbb{Z}_2 \leftarrow \begin{array}{c} - \\ \boxed{\begin{array}{c} \diagup \quad \diagdown \\ \text{red lines} \end{array}} \\ + \end{array}, \begin{array}{c} + \\ \boxed{\begin{array}{c} \diagup \quad \diagdown \\ \text{red lines} \end{array}} \\ - \end{array} \rightarrow \right / (a^2 = a, b^2 = b, ab = ba = 0)$$

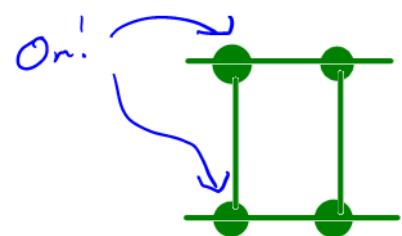

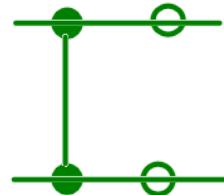

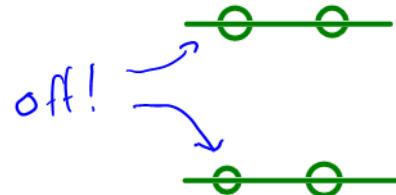

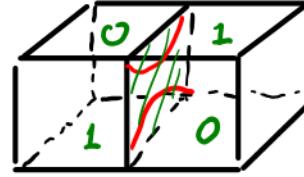

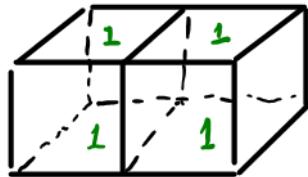

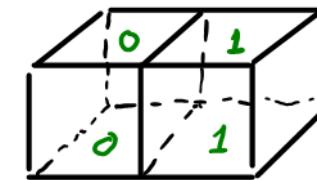

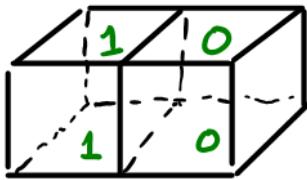

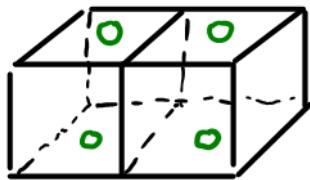

Eg 2 cubes : $Q =$

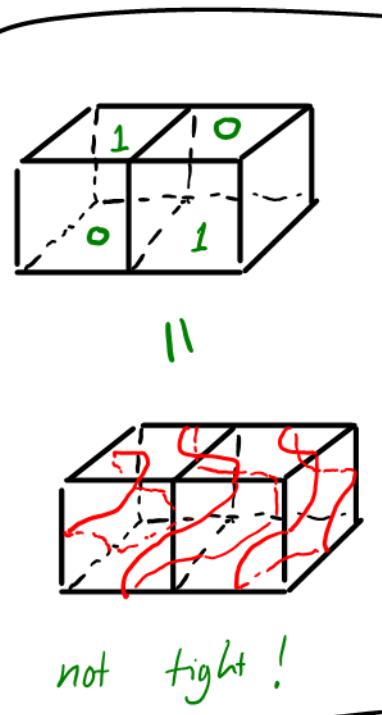

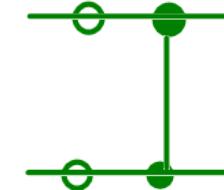

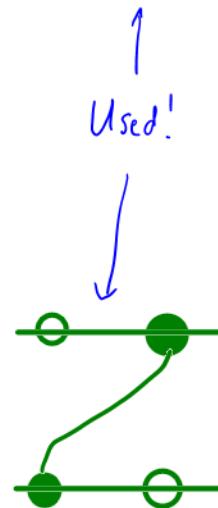

$$\begin{array}{c} + & - & + \\ \text{-} & \text{+} & \end{array}$$

TURNS OUT, there are precisely 5 s.c.c.s.

"Strand
diagrams"

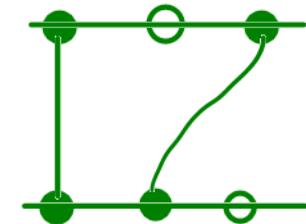

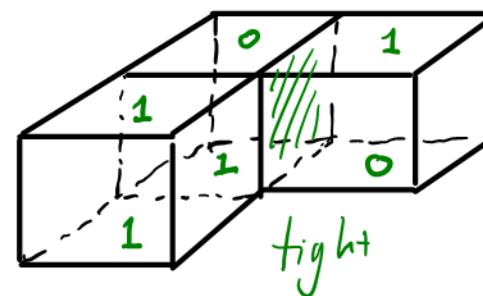

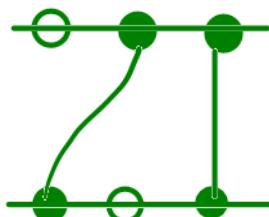

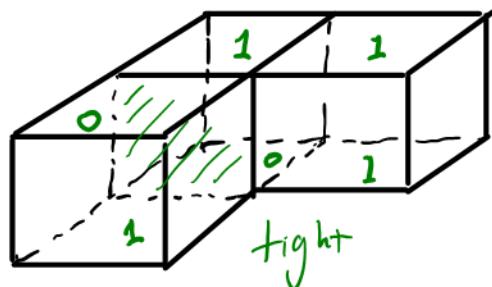

Stacking s.c.c.s = stacking strands!

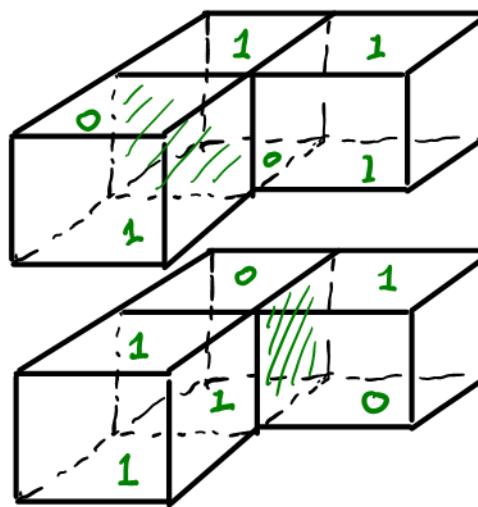

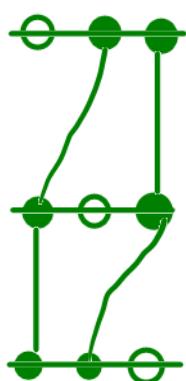

Eg 3 cakes, $Q =$

$$Q = \begin{array}{|c|c|c|} \hline + & - & + \\ \hline - & & + \\ \hline + & - & - \\ \hline \end{array}$$

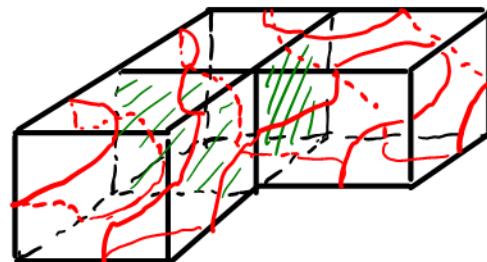

It's possible to stack tight S.C.C.S. to obtain something not tight!

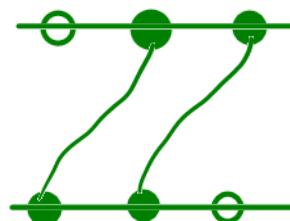

But

=

not tight!

= 0

Some elementary statements

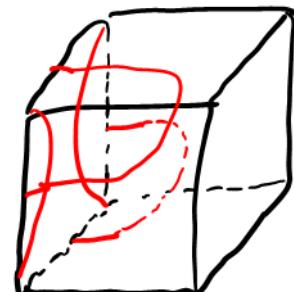

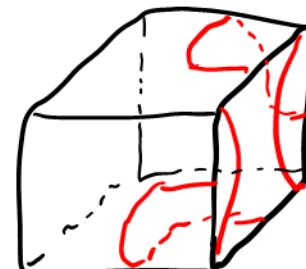

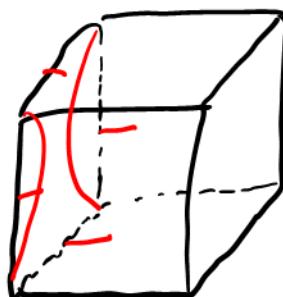

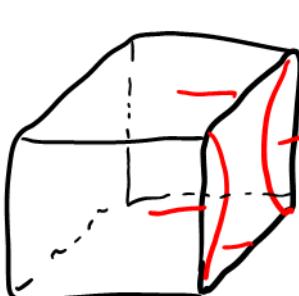

Lemma: If a s.c.c.s. is tight, then

$$\# \text{ "on squares" on top} = \# \text{ "on squares" on bottom}$$

Pf: Signs on Q mean that the curve Γ divides the boundary of the s.c.c.s. into $+, -$ regions R_+, R_- . If Γ is connected then $\chi(R_+) = \chi(R_-)$, which can be given in terms of $\#$ on/off squares. \square

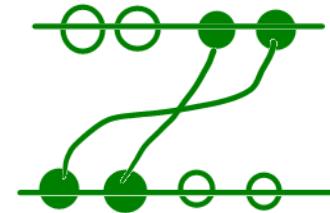

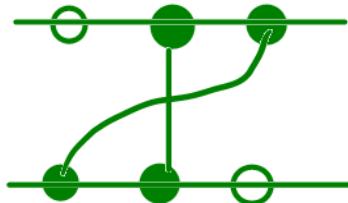

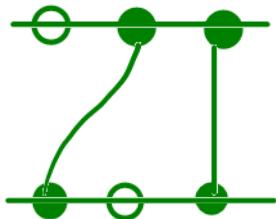

Lemma: If each cube in a s.c.c.s. is tight, then the s.c.c.s. is tight.

Pf:

Strand Algebra

A strand algebra is generated over \mathbb{Z}_2 by diagrams like

consisting of strands running between points on an interval!

Points are: on if a strand begins/ends there
+ off otherwise.

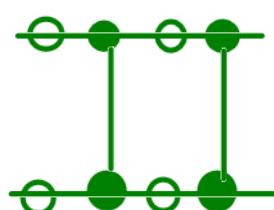

Strands never move left as they go up!

(Directionality / partial order).

Multiplication : stack strand diagrams.

(If strands don't match, 0.)

Idempotents:

strand diagrams with vertical strands only.

Strand Algebras (cont...)

More relations: Double intersection = 0.

A diagram showing two horizontal strands with four points each. In the first configuration, strands 1 and 2 cross at the second point from the left. In the second configuration, strands 1 and 2 cross at the third point from the left. Both configurations are set equal to zero.

A strand algebra also naturally has a differential: resolve crossings.

A diagram showing a strand configuration with three strands labeled 1, 2, and 3. Strand 1 crosses strands 2 and 3. The differential is shown as the sum of two terms: one where strand 1 is resolved to pass over strand 2, and another where strand 1 is resolved to pass under strand 3. A crossed-out diagram shows an attempt to resolve both crossings simultaneously, which is disallowed.

Obey Leibniz rule!

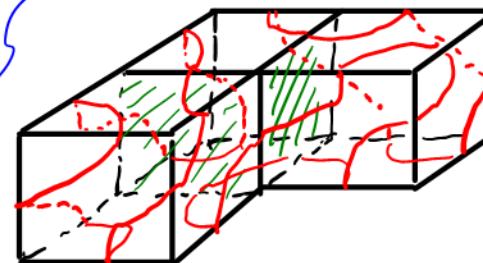

Graded by # strands / # points "on", or by # intersections of strands
→ A Differential Graded Algebra!

Strand Algebra / Contact Category Correspondence

Now

$$\text{Diagram showing two configurations of strands: one with a crossing and one without, separated by an equals sign.}$$

and recall from previously

not tight!

$$\text{Diagram showing a configuration of strands on a horizontal line, followed by an equals sign and a zero symbol, indicating the value is zero.}$$

So look at homology!

Theorem (M): Let Q be a square/cube arrangement (more generally, quadrangulated surface). Then there exists a strand algebra \mathcal{A} such that

$$CA(Q) \cong H(\mathcal{A}).$$

Note: In general the strand algebra required are slightly more complicated than the ones described here - multiple intervals, restrictions on starting/ending points, symmetrisation ...

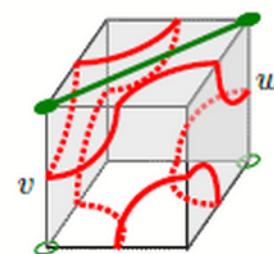

Idea of proof

Show that both $CA(\mathcal{A})$, $H(\mathcal{A})$ are "determined locally"

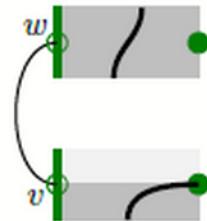

and show that these local parts match up.

Cubes \longleftrightarrow strands (with $\lambda = 0$, up to boundaries)

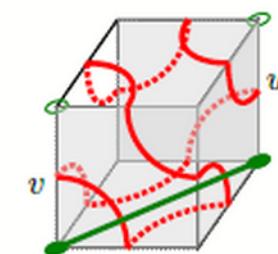

(Use results of
Lipshitz - Ozsváth - Thurston,
ideas of Zarev.)

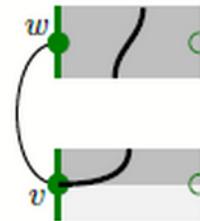

Side after v unused
Top on, bottom off

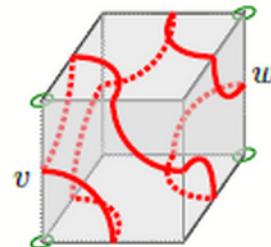

$v \in \partial^+(\text{supp } h)$
 $w \in \text{Int}(\text{supp } h)$
 $M(v) \in t \setminus s$

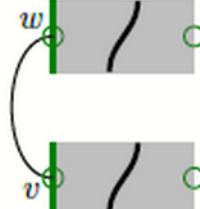

Side before v unused
Top off, bottom on

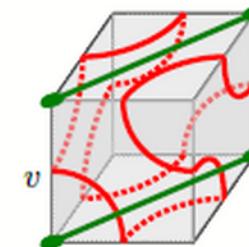

$v \in \partial^-(\text{supp } h)$
 $w \in \text{Int}(\text{supp } h)$
 $M(v) \in s \setminus t$

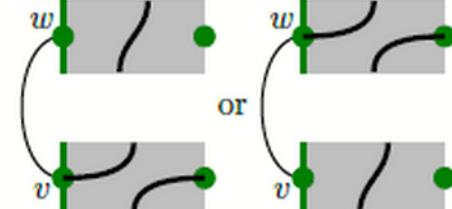

All sides used
Top, bottom off

$v, w \in \text{Int}(\text{supp } h)$
 $M(v) \notin s \cup t$

All sides used
Top, bottom on

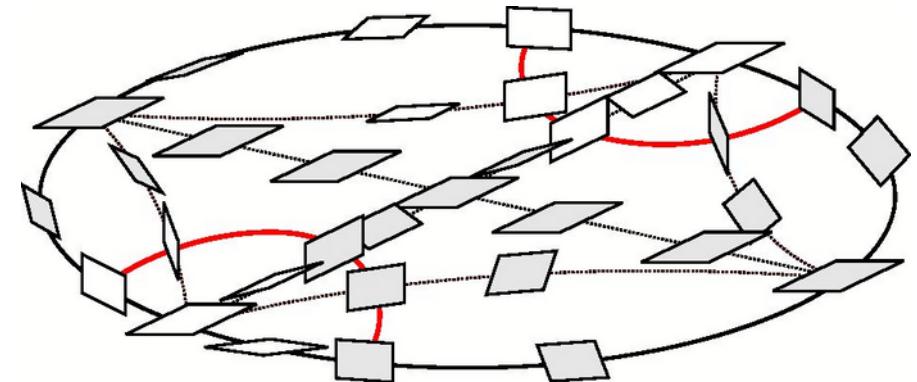

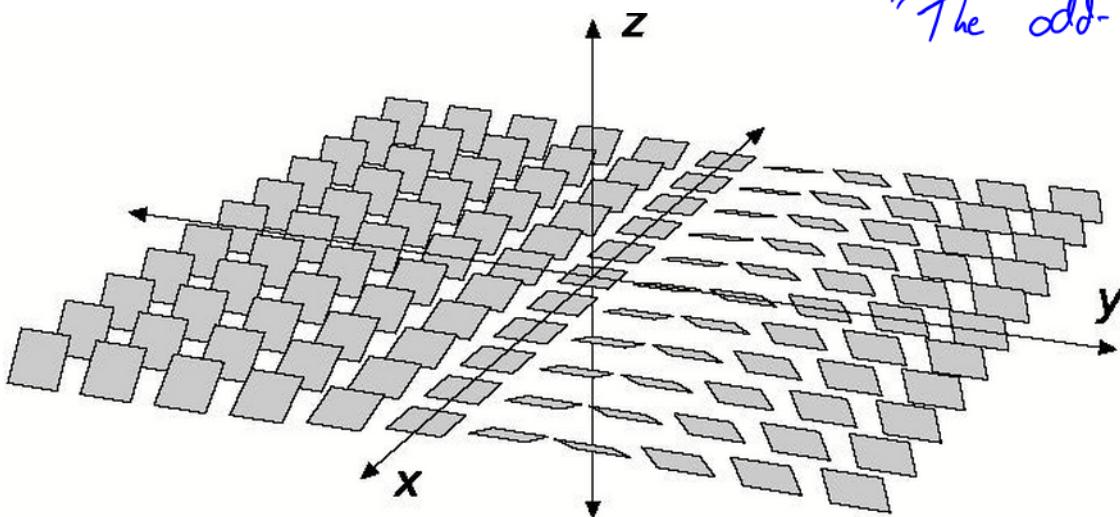

$v, w \in \text{Int}(\text{supp } h)$
 $M(p) \notin s \cup t$

Context, motivation, remarks

- * Calculated contact structures are a combinatorial version of contact structures.

A contact structure on a 3-manifold is a non-integrable 2-plane field.
"The odd-dimensional version of symplectic geometry."

- * So we have (a) reduced differential geometry to combinatorics,
(b) precisely described how they combine.

Context, motivation, remarks (cont.)

Strand algebras were actually introduced to describe something apparently completely different!

Lipshitz-Ozsváth-Thurston: Bordered Heegaard Floer homology

- * A powerful invariant of 3-manifolds with boundary M defined by analysing holomorphic curves in an auxiliary 4-manifold $\Sigma \times I \times \mathbb{R}$
- * Strand algebras encode asymptotic behaviour of holomorphic curves near ∂M .

Contact geometry is known to have many connections to Heegaard Floer theory ... this is a new one

"Geometry of holomorphic boundary asymptotics = Contact geometry near boundary surface"
